Genital warts

Condylomata acuminata (or genital warts¹) is one of the most prevalent sexually transmitted infections (STI). It is caused by human papillomavirus, mostly HPV 6 and 11, with HPV 6 being the most frequent. The warts are generally found in the anogenital area². In women, lesions are found around the vagina, but may even affect the cervix³, while in men they are found on the glans penis. In both sexes, warts can be found around the anus.

The infection is passed on⁴ via⁵ skin-to-skin contact, especially during vaginal and anal sexual intercourse⁶. People can also contract the disease by sharing⁷ sex toys. Oral sex rarely leads to⁸ infection by this virus, but the virus can be passed on from mother to infant⁹ during childbirth¹⁰. It's important to know that you can't get genital warts from kissing, sharing towels¹¹ or from toilet seats.

Symptoms of genital warts include painless¹² growths¹³ around the vagina, penis or anus, which may itch¹⁴ or bleed¹⁵, and you may notice that the urine jet is deviated from its usual trajectory (sideways¹⁶, for instance). Nonetheless¹⁷, there may be no symptoms whatsoever¹⁸.

A visual examination of the lesions is usually sufficient to diagnose the disease.

There are a number of treatments available and these include surgery; the warts can be excised or burnt off with a laser, which may cause scarring¹⁹. Alternatively, they can be frozen²⁰, though this treatment has to be repeated every week for about 4 weeks. There are also ointments²¹ or liquids that need to be applied to the warts several times a week until they shrivel up²² and disappear.

Despite these treatments, the virus may not be eradicated and may be passed on even if there are no apparent warts, and the warts may reappear. In some cases, the body may clear²³ the virus over time.

The common wart treatments from a pharmacy are not suitable²⁴ for genital warts.

Unfortunately, it may not be possible to know who contaminated you with the virus or how long you've been infected with the virus.

Prevention is essential, and the sexual partners of people with genital warts should be screened for²⁵ the condition. Sexual intercourse should be avoided²⁶ until the warts have totally disappeared, but if this is not possible, a condom²⁷ should be worn. In fact, it is advisable²⁸ to use a condom every time you engage in vaginal, anal or oral sex.

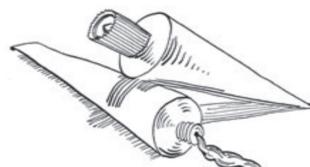

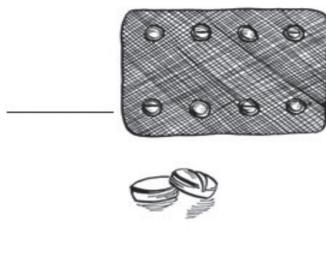

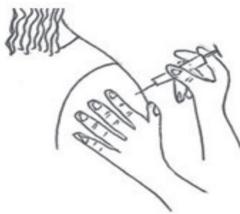

The HPV vaccine, which is now generally available to protect women against cervical cancer, also provides protection against genital warts.
